DEDICATION/ACKNOLEDGEMENTS

I would like to dedicate this work to Professor Ian C Reid who was a mentor, friend and great scientific mind. Without him I would not be where I am today, even if we did debate where that place should be.

There are many people who made this work possible. Linda, I have to thank you for taking a chance on a young scientist “turning to the dark side”, and introducing me to MBT. This thesis would not have been possible without your enthusiasm and guidance. Malcolm, thank you for your supervision and encouragement, you helped to keep me going when I was fed up. Kristy-Anne, Andrea, Maggie and Emma, thank you for allowing me to join your HUB team. Your wisdom and laughter helped to make this research possible and worthwhile. I also need to thank my participants from the HUB program, without your openness and willingness to take part in the research this thesis would not have been possible.

To my academic supervisors Angus and Matthias, thank you for your support through the rough times and your guidance.

Gordon, thank you for being there and supporting me through my second thesis roller coaster, even though I had said never again after my PhD. Your wisdom and never ending encouragement kept me smiling throughout.

THESIS ABSTRACT

Introduction: Borderline Personality Disorder (BPD) is characterised by deficits in affect and impulse regulation, along with interpersonal difficulties (Lieb et al., 2004). It is thought to develop through a complex relationship between adverse childhood events, such as childhood abuse and genetics. A recent developmental model of BPD and one that is gaining popularity focuses on mentalization. Following their exposition of the mentalizing model of BPD, Bateman and Fonagy developed the Mentalization Based Treatment (MBT) intervention for BPD (Bateman & Fonagy 2006). This intervention includes both group and individual therapy with the focus on the patient’s relationship with the therapist and other members of the group. Promising evidence that MBT interventions are effective for treating symptoms of BPD is beginning to emerge.

Methods: First a systematic review examining the prevalence of childhood abuse in BPD patients was conducted. Second, an empirical study of the efficacy of a group-only adaptation of the MBT intervention for BPD, delivered in a routine health service setting. Finally, planned exploratory analyses were conducted in order to ascertain what factors might predict group completion.

Results: The results of the systematic review suggested that that emotional abuse (mean prevalence 63%) and emotional neglect (mean prevalence 63.1%) are the most common forms of abuse reported by this population followed by physical neglect (mean prevalence 40.89%), sexual abuse (mean prevalence 36.9%) and physical abuse (mean prevalence 32.49%). The results of the second study revealed that the HUB is an acceptable treatment to participants, with indicators of treatment efficacy in relation to reducing overall psychiatric symptoms along with specific symptoms including interpersonal sensitivities, depression, phobic anxiety and paranoid ideation. Finally, exploratory analyses suggested that patients who were older and with less histrionic symptoms (as defined by the Personality Disorder Questionnaire-4) were more likely to complete the HUB.

Conclusions: These findings demonstrate that a group-only MBT intervention displays promising effectiveness in treating core symptoms of BPD and is acceptable to patients. Further it suggests that
group-only MBT interventions are worth continued investigation both into their efficacies and the potential efficiencies associated a group-based intervention.
PAPER 1: SYSTEMATIC REVIEW

TITLE: A systematic review of the prevalence of childhood abuse in individuals diagnosed with Borderline Personality Disorder

ABSTRACT

Borderline Personality Disorder (BPD) is characterised by deficits in affect and impulse regulation, along with interpersonal difficulties (Lieb et al., 2004). It is thought to develop through a complex relationship between adverse childhood events, such as childhood abuse and genetics. While research has examined the prevalence of childhood abuse in patients with BPD there have been no recent systematic reviews of meta-analyses examining the prevalence of different forms of childhood abuse. The current paper sought to systematically review the literature in order to examine the prevalence of childhood abuse in individuals with BPD. The results of the review suggest that emotional abuse (mean prevalence 63%) and emotional neglect (mean prevalence 63.1%) are the most common forms of abuse reported by this population followed by physical neglect (mean prevalence 40.89%), sexual abuse (mean prevalence 36.9%) and physical abuse (mean prevalence 32.49%). The results also highlighted that while the quality of the papers was generally of a high standard; measures of abuse varied greatly and may have a large impact on reported prevalence rates.

KEYWORDS

Borderline Personality Disorder, Childhood Abuse, Sexual Abuse, Emotional Abuse
INTRODUCTION

Borderline Personality Disorder (BPD) is considered to be a serious mental health difficulty that can be hard to treat and manage (Zanarini et al., 2005). This disorder is characterised by unstable impulse and affect regulation, as well as unstable self-image and interpersonal relationships (Lieb et al., 2004). Individuals with BPD are more likely to experience interpersonal difficulties, violence at work, sexual abuse, homelessness and problems with the police (Coid et al., 2009). Epidemiological research has estimated that the prevalence of BPD can range from 0.7% in Norway; (Torgersen et al., 2001) to 1.3% in the United Kingdom (Coid et al., 2009) and 1.8% reported in the United States of America (Swartz et al., 1990). Patients who are diagnosed with BPD often also meet the criteria for other disorders, such as major depression, substance misuse, and anxiety disorders (Oldham et al., 1995; Zanarini et al., 1998; Zimmerman & Mattia, 1999; McGlashan et al., 2000).

Childhood trauma has been shown to be quite prevalent among the general population. A UK survey found the prevalence of childhood sexual abuse to be 10% (May-Chahal & Cawson, 2005). A more recent survey in the UK found that 17% of women and 8% of men reported experiencing any form of sexual abuse before the age of 16 (Bebbington et al., 2011). These figures are important as links have been found between experiencing childhood trauma and development of mental health difficulties. For example, Cutajar and colleagues (2010) found that exposure to childhood abuse increased the risk for psychosis, affective disorders, anxiety, substance misuse and personality disorders. Beddington and colleagues (2004) also found an association between childhood sexual abuse and psychotic symptoms in a UK-based population study.

Why individuals develop BPD is still not clearly understood, but it is thought to involve a complex relationship between genetics, adverse childhood events, and interpersonal difficulties. One of the most prominent models of BPD development is Linehan’s biosocial model (Linehan 1993). This model proposes that BPD is the result of a combination of an individual’s biological predisposition to emotion regulation/interpersonal difficulties and an invalidating social environment during childhood. More recent models have carried on with this theme; Hughes and colleagues (2012) proposes that the
development of BPD may be due to a child’s lack of social proximity to or responsiveness from relevant caregivers, which leads to a disruption in an individual’s ability to effectively regulate their emotions. In parallel, developmental theories focus on early attachment and early childhood experiences (Bateman & Fonagy, 2006). These theories suggest that the attachment system is disorganised in BPD resulting in the disorganisation the individual’s self-structure (Bateman & Fonagy, 2006).

Common to the above theories is the positioning of childhood adversity as integral to the development of BPD. Research over the past few decades has begun to elucidate this relationship by examining whether there are certain types of adversity which have a higher link with BPD. For example, Briere and Elliot (2003) found that childhood emotional abuse was the best predictor of a BPD diagnosis in men, while sexual and physical abuse were not significant predictors. This result was replicated by Bornovalova and colleagues (2006). Watson et al. (2006) also found that emotional abuse and neglect were correlated with dissociative symptoms in individuals with BPD, while no such relationship was found with other forms of abuse.

Difficulties with emotion regulation are a core symptom of BPD and researchers have examined the relationship with childhood abuse and emotional regulation. Multiple studies have found that children with a history of abuse are more likely to have difficulties with emotion regulation than children who have not experienced abuse (Shields & Cicchetti 1998; Shipman et al., 2000; Shipman et al., 2005). Further, childhood abuse has been found to correlate with higher levels of emotional non-acceptance (Gratz et al., 2007) and lower levels of emotional understanding (Shipman et al., 2000).

**Aims of the review**

While there are many individual studies spanning the decades which have examined the prevalence of childhood abuse experienced by individuals with BPD (Huang et al., 2012; Battle et al., 2004; Ogata et al., 1990; Oldham et al., 1996), there are no recent systematic reviews or meta-analyses consolidating the knowledge gained from these individual studies.
The aim of this review was to systematically identify, synthesise and critically evaluate the literature on the prevalence of childhood abuse amongst individuals with BPD. The main research question was would there be differences in reported prevalences of different forms of abuse in individuals diagnosed with BPD. Secondary research questions considered a) consideration of sources of methodological bias in the literature that could impact on prevalence figures and b) identification of potential covariates that could also impact on prevalence rates.

MATERIALS AND METHODS

Inclusion and exclusion criteria

The inclusion criteria for this review include (i) measure of childhood emotional or sexual abuse, (ii) participants diagnosed with Borderline Personality Disorder, (iii) were published between 1980 (when BPD entered the Diagnostic and Statistical Manual of Mental Disorders; DSM) and December 2014, (iv) written in English, (v) large-scale (more than 20 participants) studies.

The exclusion criteria for this review were (i) non-clinical studies, (ii) single case studies or case series, (iii) no measure of childhood sexual or emotional abuse, (iv) qualitative data, (v) conference abstracts, (vi) book chapters, (vii) unpublished studies or dissertation abstracts, and (viii) papers not published in English.

Search Strategy

Computerised databases were searched to find relevant articles, which investigated the prevalence of childhood sexual or emotional abuse in individuals with Borderline Personality Disorder. In order to conduct this search the following search terms were used in the subject headings: “Borderline Personality Disorder” or “Borderline Traits” or “Borderline Personality”, combined with “childhood trauma” or “childhood abuse” or “sexual abuse” or “emotional abuse”. The three databases used in this search were PsychInfo (1980 to December 2014), Medline (1980 to December 2014) and EMBASE (1980 to December 2014). 1980 was chosen as a start date as this was the year that BPD
entered the DSM-III. Neglect has only recently become a subject of interest in this area and a preliminary search did not produce any papers of interest, therefore neglect was not used as an official search term in this review. It is likely however, that in the future neglect will be a relevant term for this type of review.

Once the searches were complete duplicates were removed before titles and abstracts were reviewed. Articles that did not meet the inclusion criteria at this stage were discarded and the full text of articles that were potentially eligible was obtained.

Quality Criteria

All of the selected articles were then assessed to evaluate their quality and potential for bias. These criteria were based on the STROBE statement for cohort/cross sectional studies (von Elm et al., 2008) and assessed a number of different criteria from how childhood abuse was measured to sample size considerations. Each criterion was rated as high, moderate or low as suggested by Khan and colleagues (2003). In brief, the following criteria were assessed: childhood abuse measurement, BPD measurement, study design, setting, variables, bias, and sample size consideration. The two which were considered to be the most important to the review were how childhood abuse and BPD were measured. The criteria for these two factors were:

Childhood abuse: (i) High - Use of the Childhood Trauma Questionnaire (CTQ); (ii) Moderate- Use of another validated questionnaire or interview; (iii) Low - Use of non-validated questionnaires or simply asking if it had occurred during interview.

BPD: (i) High- use of the Structured Clinical Interview Diagnostic –II (SCID-II); (ii) Moderate - use of another validated questionnaire; (iii) Low - use of only clinical impression.

For Childhood Abuse, the CTQ was assigned the highest rating as the instructions and test-items are largely phrased in terms of concrete, objective events and behaviours. Further, terms such as trauma, abuse and neglect are avoided due to their subjective, evaluative and stigmatizing qualities, which can
arouse defensiveness (Bernstein et al., 1994). This is an advantage of this approach avoiding these terms is hypothesised to maximise the accuracy of recall (Brewin et al., 1993). For BPD diagnosis the SCID-II was assigned the highest rating as this interview has become the gold standard in research for confirming diagnoses of personality disorder. Further, research has shown that this interview has good internal consistency and inter-rater reliability (Maffei et al., 1997; Lobbestael et al., 2010).

The other criteria were rated as follows:

Study Design: (i) High – clearly described in detail early in the paper, making it straightforward to replicate the study. (ii) Moderate – Lacking some clarity or details making it necessary to do further reading in order to replicate the study. (iii) Low – Not well described or insufficient detail that it could not be replicated.

Setting: (i) High – Setting, locations and relevant dates including period of recruitment are all clearly detailed. (ii) Moderate – Setting and locations documented but dates not clearly indicated. (iii) Low – Settings, locations and dates are not clear or not reported.

Variables: (i) High – Variables are all clearly defined (including outcomes, predictors and potential confounders) and diagnostic criteria are clearly stated. (ii) Moderate- An attempt at defining variables but some detail is missing. (iii) Low – No attempt at defining variables.

Bias: (i) High – Potential sources of bias are discussed and efforts to reduce bias are clearly described. (ii) Moderate – An attempt is made at discussing sources of bias but no efforts are made to reduce it. (iii) Low – No discussion of potential bias.

Study Size: (i) High – Study size is based on a well described power calculation. (ii) Moderate- An attempt is made to describe how the study size was determined. (iii) Low – No rationale for study size is reported.

All articles were rated using an extraction sheet (Appendix B) which included the above variables by two independent reviewers. Any disagreements were resolved by discussions between the two
reviewers. If any disagreements could not be resolved then an adjudicator was consulted to make the final decision.

RESULTS

Literature Search

The search and exclusion process is summarised in Figure 1. We identified 97 potential papers for review. Of these, 74 were excluded based on the inclusion/exclusion criteria. The reasons for exclusion are as follows: abuse prevalence not reported \((n=36)\), no measure of Borderline Personality Disorder \((n=5)\), abuse type not specified \((n=1)\), no abuse measure defined \((n=4)\), used only BPD patients who had auditory hallucinations \((n=1)\), Borderline Personality Disorder not reported separately from other personality disorders \((n=6)\), review of the literature \((n=1)\), less than 20 participants \((n=3)\), same sample reported in multiple papers \((n=6)\), non-clinical sample \((n=1)\), only one gender in sample \((n=9)\). Based on this search strategy 23 papers met the criteria for review and are included in this systematic review.

Single gender studies were excluded for two main reasons. First, it is possible that gender differences may exist in the development of BPD. Therefore, including studies with only one gender could skew the results by either under-or over-playing the importance of childhood trauma in the development of this disorder. Second, this review aimed to provide an initial general examination of the prevalence of different forms of abuse in individuals with BPD, therefore, both genders were included to attempt to make the sample as representative as possible. A table detailing these excluded studies can be found in Appendix C.
Medline, Psychinfo and EMBASE searched for keywords in December 2014

1194 articles found (duplicates removed)

477 papers excluded as title not relevant.

717 abstracts were then reviewed against inclusion and exclusion criteria.

620 papers were excluded based on criteria.

After abstract review 97 papers were deemed fit for further review and full texts were obtained.

74 papers excluded based on criteria.

23 papers met the inclusion criteria and are included in this review.

Figure 1: Flowchart of the article selection process (breakdown of exclusions in main text).

Table 1: Summary of included studies. The following abbreviations were used: SA = sexual abuse, EA = emotional abuse, PA= physical abuse, VA= verbal abuse, EN = emotional neglect, PN = physical neglect.

*Not able to quantify means that samples included more than one personality disorder type and only overall gender splits rather than per diagnosis were provided.
Overall, there were 2,612 participants in the included studies. Based on the data from 18 papers the average age was 33.37 years (Watson et al., 2006; Martin-Blanco et al., 2014; Huang et al., 2012; Ogata et al., 1990; Johnston et al., 2009; Figueroa et al., 1997; Wong et al., 2010; Kingdon et al., 2010; Fernando et al., 2014; Golier et al., 2003; Zanarini et al., 2005, 2000, 1989; Wagner et al., 2009; Soloff et al., 2008, 2002; Links et al., 1988; Brodsky et al., 1995; Zweig-Frank & Paris, 2002), with 5 papers not reporting on the age of participant (n=555, 21% of participants: Battle et al., 2004; Zhang et al., 2013; Bandelow et al., 2005; Oldham et al., 1996). 16 studies reported on the gender split of their participants and based on this data, 81% (n=1,372) of participants were female and 19% (n=322) were male (Watson et al., 2006; Martin-Blanco et al., 2014; Huang et al., 2012; Ogata et al., 1990; Johnston et al., 2009; Figueroa et al., 1997; Wong et al., 2010; Kingdon et al., 2010; Fernando et al., 2014; Zanarini et al., 2005, 1989; Wagner et al., 2009; Soloff et al., 2008, 2002; Links et al., 1988; Zweig-Frank & Paris, 2002). The other 7 papers did not report this data, which accounted for 35% (n=918) of all participants (Battle et al., 2004; Zhang et al., 2013; Bandelow et al., 2005; Oldham et al., 1996; Golier et al., 2003; Zanarini et al., 2000; Brodsky et al., 1995).

All studies recruited from either inpatient or outpatient services or by public advertising number. Nine papers recruited participants from outpatient clinics (n=883), 7 papers recruited participants who were inpatients at psychiatric hospitals (n=864), 2 papers recruited both inpatients and outpatients (n=182), 2 papers recruited from outpatient clinics of general hospitals (n=262). In 2 papers it was unclear where participants were recruited (n=314), and in 1 paper participants were recruited both from outpatient clinics and advertisements in the surrounding community (n=151).

Measurement

Childhood Abuse

Six papers used the Childhood Trauma Questionnaire (CTQ) to measure self-reported levels of childhood abuse (Watson et al., 2006; Zhang et al., 2013; Johnston et al., 2009; Kingdon et al., 2010;
The types of abuse measured by this questionnaire include sexual, emotional and physical abuse, as well as emotional and physical neglect. Of these 6 studies, 5 used the regular form and one used the CTQ short form. Other self-report questionnaires that were used included the Childhood Experience of Care and Abuse Questionnaire (CECA-Q: Huang et al., 2012), Patient History Questionnaire (Oldham et al., 1996), the Trauma History Questionnaire (Golier et al., 2003), Retrospective Family Pathology Questionnaire (Zanarini et al., 1989) the Retrospective Separation Experiences Questionnaire (Zanarini et al., 1989), the Sexual Experiences Questionnaire (Brodsky et al., 1995) and the Developmental Experiences Questionnaire (DEQ: Zweig-Frank & Paris, 2002). Two of the studies used their own self-report questionnaires (Bandelow et al., 2005; Links et al., 1988). Standardised interviews were also used to measure childhood abuse and included the Familial Experiences Interview (Ogata et al., 1990; Figueroa et al., 1997), Abuse History Interview (Zanarini et al., 2005), the PTSD section of the Munich Composite International Diagnostic Interview (Wagner et al., 2009), Abuse History adapted from the Dissociative Disorder Interview Schedule (Soloff et al., 2008, 2002), and the Childhood Experiences Questionnaire – Revised (CEQ-R: Battle et al., 2004; Zanarini et al., 2000). Finally one paper simply asked whether an individual had experienced any childhood abuse during interview (Wong et al., 2006).

**Borderline Personality Disorder**

In order to confirm that participants fit the criteria for Borderline Personality Disorder various interviews and questionnaires were used. The Structured Clinical Interview Diagnostic (SCID-II) was used by 10 papers (Martin-Blanco et al., 2014; Huang et al., 2012; Zhang et al., 2013; Johnston et al., 2009; Bandelow et al., 2005; Wong et al., 2010; Kingdon et al., 2010; Fernando et al., 2014; Wagner et al., 2009; Brodsky et al., 1995). Of these papers Martin-Blanco et al used the Spanish version, Wong et al the Chinese version, and Bandelow et al along with Wagner et al used the German version. The Diagnostic Interview for Borderlines (DIB) and its revision DIB-R, another structured interview, was used in 9 papers (Ogata et al., 1990; Figueroa et al., 1997; Zanarini et al., 2005; Zanarini et al., 2000; Zanarini et al., 1989; Soloff et al., 2008; Soloff et al., 2002; Links et al., 1988; Zweig-Frank & Paris, 2002). The Diagnostic Interview for DMS-IV PDs (DIPD-IV) was used by one
paper (Battle et al., 2004) The Personality Disorder Questionnaire (PDQ), a self-report questionnaire was also used by 3 papers (Watson et al., 2006; Zhang et al., 2013; Oldham et al., 1996).

**Abuse Prevalence**

Prevalence of childhood sexual and emotional abuse varied quite substantially across studies. Sexual abuse prevalence ranged from 4.5% to 78.7% (mean of 36.9%), while emotional abuse prevalence ranged from 33% to 94% (mean of 63.2%). Emotional neglect prevalence ranged from 44.5% to 90% (mean of 63.1%) and was reported in 6 papers. While sexual abuse was reported in all 23 papers, emotional abuse was only reported in 9 of the papers. Physical abuse was reported in 19 of the papers and prevalence ranged from 15% to 61.4% (mean of 32.49%). Finally physical neglect was reported in 8 papers with prevalence ranging from 17% to 69.1% (mean of 40.89%). Prevalence figures from all the reviewed papers can be found in Table 1.

It is also possible that culture may play a role in abuse prevalence. In this review papers covered people from Asia (3 papers), Europe (6 papers), North America (13 papers) and one from Australia. For the European sample, sexual abuse prevalence ranged from 32.7% to 73.9% (mean of 52.8%), Asian sample prevalence ranged from 22.2% to 30% (mean of 24.9%), North American sample prevalence ranged from 4.5% to 90% (mean of 28.5%), and for Australia it was reported to be 43%. Emotional abuse ranged from 57.1% to 94% (mean of 70.75%) in Europe, was only reported once in Asia (prevalence 44.4%), ranged from 33% to 71.4% (mean of 56.8%) in North America and was reported to be 71% in the Australian sample. For physical abuse prevalence ranged from 30.6% to 52% (mean of 41.1%) in Europe, from 33% to 46.8% (mean of 38.7%) in Asia, from 15% to 61.4% (mean of 31.24%) in North America and was reported to be 39% in Australia. For emotional neglect prevalence ranged from 44.5% to 90% (mean of 63.8%) in Europe, was only reported once in Asia (prevalence of 52.8%), was not reported in the North American studies, and was reported to be 71% in Australia. Finally for physical neglect prevalence ranged from 21.1% to 57% (mean of 43.5%) in Europe, was reported once in Asia (prevalence of 69.1%), ranged from 17% to 24% (mean of 20.5%) and in the Australian sample was reported to be 43%.
Quality Review of Papers

The results of the quality review of the included papers can be found in Table 2. The results of this quality assessment revealed that many of the papers were of a high standard. All 23 studies scored low for study size, with not one explaining why they recruited the number of participants that they did.

Five papers achieved high ratings on both of the main criteria of interest (Martin-Blanco et al., 2014; Zhang et al., 2013; Johnston et al., 2009; Kingdon et al., 2010; Carvalbo Fernando et al., 2014). For these papers there was less variance in prevalence of moderate to severe levels of both sexual and emotional abuse, sexual abuse prevalence ranged from 22.5% to 63% and emotional abuse prevalence ranged from 44.4% to 94%. There was also less variance for physical abuse and neglect ranging from 30.6% to 52% and 21.1% to 69.1% respectively. Interestingly, there was no change to the prevalence range for emotional neglect when only taking into account these papers. As all these figures are for moderate to severe abuse it is likely that the prevalence levels would be much higher for milder levels of abuse.

Seven papers were rated as having moderate ratings on their measure of childhood abuse. Of these studies only three (Battle et al., 2004; Zanarini et al., 2000, 2005) reported prevalence for both sexual and emotional abuse, ranging from 4.5% to 31.4% and from 33% to 71.4% respectively. The highest prevalence levels of both forms of abuse come from Zanarini and colleagues’ (2005) which used, the Abuse History Interview to assess prevalence. During this interview patients are provided with examples of each form of abuse and participants were asked to describe their own experiences. The lowest reported incidence of both sexual and emotional abuse was reported by Zanarini et al (2000), which used the CEQ-R. This semi-structured interview requires detailed information around the event in question to receive a positive rating, therefore relying on the participant’s willingness to disclose sensitive memories and their memory for events that may have occurred many years ago, which could artificially lead to lower prevalence rates. Looking at these papers in regards to other forms of abuse and neglect none of them reported on emotional or physical neglect. For physical
abuse it was the Trauma History Questionnaire which produced the highest prevalence rate of 52.8% (Golier et al., 2003) while again it was the CEQ-R which produced the lowest prevalence rate of 24% (Zanarini et al., 2000).

None of the reviewed papers received low ratings for both these main criteria, childhood abuse and BPD diagnosis, however 10 papers did receive low ratings for their measures of child abuse (Ogata et al., 1990; Bandelow et al., 2005; Wong et al., 2010; Oldham et al., 1996; Zanarini et al., 1989; Wagner et al., 2009; Soloff et al., 2008 & 2002; Links et al., 1988; Brodsky et al., 1995). Of note, none of these papers reported prevalence of emotional abuse or neglect, but for sexual abuse prevalence ranged from 25.9% to 71%. Physical abuse was reported in 7 of these papers ranging from 15% to 61.4% and physical neglect was reported in 2 of the papers. No papers received low ratings for their measure of BPD.

On the methodological criteria only one study, Battle et al. (2004), achieved a high rating for both discussing potential bias and trying to control for it. The rest of the papers scored a moderate level indicating that while bias was discussed, nothing had been done to try and limit it. This suggests that bias is not being thought of until after the study has been conducted. This interpretation is supported by the fact that bias was only discussed as a study limitation in most papers. Overall, the included papers scored well for study design, setting and variables, making them on a whole fairly easy to replicate.

Table 2: Ratings of the individual papers included in this review.
DISCUSSION

The results of this review suggest that emotional abuse, followed by sexual abuse are the most prevalent abuse types among individuals with BPD. Based on the reviewed literature, it appears that there has been more research into sexual abuse than emotional abuse. This might be due to the trend in research to examine the contribution of childhood sexual abuse to adult behaviour and psychiatric pathology, which began in the 1980s (Figueroa et al., 1997). Further, sexual abuse had been found to discriminate between individuals with BPD from other psychiatric diagnoses (Weaver & Clum, 1993). This review however highlights the vast range in reported sexual abuse, ranging from as little as 3.5% to at most 71%, with a mean of approximately a third. This raises some important questions: does how sexual abuse is measured impact on prevalence figures and, what role does it play in the development of BPD? Further it also raises the question as to why emotional abuse is not the main focus in more studies given the high prevalence rates reported when it is measured. These aspects of the review will be explored further below.

In this review the lowest prevalence figures for sexual, emotional and physical abuse (Zanarini et al., 2000) came from an interview-based measures, (CEQ-R), rather than self-report questionnaires. It is possible that either participants’ did not feel comfortable disclosing histories of abuse to an interviewer they had just met or it may be that the detail required to achieve a positive rating was at too high a threshold. Support for the latter interpretation (threshold rather than level of comfort) can be evidenced from observation that the highest prevalence of sexual abuse also came from an interview measure, the Family Experiences Interview (Zanarini et al., 2005). In this interview questions are more structured and it relies less on the participant spontaneously recalling detailed examples. Another factor which may have contributed to this discrepancy may be the interviewer’s technique. It is possible that the interviewers used for Zanarini and colleagues (2005) study were more
experienced and had the skill of putting people at ease. That combined with the structure of the questions may have led to this discrepancy. Future research could be to compare the prevalence rates using these two interviews would be of benefit.

Another important finding from this review is that the measurement tool used to measure childhood sexual abuse and emotional abuse can have a large influence on prevalence figures. As detailed above, thresholds, and directedness of the questions may contribute to these large variances in prevalence. On the other hand, perhaps high prevalence rates from self-report measures are due to over-reporting or that self-reports provide the protection of anonymity to enable disclosure. Further research however would be needed to test these theories. Nonetheless, it does highlight the need for researchers to justify why they have chosen the measure they have, and the need to consider the measure as a potential source of bias. This is also important given that there is currently no recognised gold standard for measuring childhood abuse.

While it may be possible that culture could affect prevalence results it is difficult to judge its role from this review. This is due to issue raised above of measurement choice. The CTQ was mostly popular in Europe, while more interview style ratings were used in North America. This makes it difficult to compare the prevalence results as we know that the measure can also have a great effect on results. Further there was an uneven cultural representation of the included studies, with the majority of studies originating from North America. In order to address the potential impact of culture, studies using the same measures of abuse across countries would be required.

The role which sexual abuse may play in the development of BPD has been questioned over the last fifteen years as research has shown that 20 to 45% of individuals with BPD do not report histories of childhood sexual abuse (Goodman & Yehuda, 2002). Further, a meta-analysis conducted by Fossati and colleagues (1999) found only a moderate association
between childhood sexual abuse and BPD. Our findings provide support Fossati et al.’s meta-analysis (1999) with, on average, only 30% of individuals across 23 studies who reported suffering childhood sexual abuse. This raises the question, if sexual abuse is not a sufficient predictor for the development of BPD then what is? Research has begun to reveal that sexual abuse does not often occur in isolation, and that individuals with BPD are more likely to have experienced multiple forms of abuse, which is often more severe and frequent than individuals without BPD (Laporte & Guttman, 1996). Therefore, other types of abuse to form an important role in the development of BPD and research began to examine this in more detail.

Emotional abuse in this review had a more restricted range from 44% to 94% (compared to 4.5% to 78.7% for sexual abuse) and appeared to be more prevalent than sexual abuse, with a mean prevalence of 63.2% compared to 36.9%. Past research that has found emotional neglect to be a strong predictor of BPD (Sabo 1997). The current paper supports Sabo’s 1997 findings with high levels of emotional abuse (63.2%) and neglect (63.1%) reported. This also meshes well with both the attachment based theories and Linehan’s theory of BPD, which both propose that disruption to a child’s social and emotional world lead to disruption in emotional regulation. Therefore if emotional abuse or neglect and later emotional regulation are important features of BPD then treatments geared to tackle these features may have some effect.

The results also support both the theoretical and treatment rationale for intervention approaches that give prominence to the role of childhood trauma within the development and maintenance of BPD. For example, Bateman and Fonagy’s developmental model centres on the ability to mentalize, which is the ability to hold someone else’s mind in your mind (Bateman & Fonagy, 2006). In their theory early disruption of the attachment system, which is often due to childhood abuse or neglect, leaves individuals with BPD with a lower threshold for the activation of the attachment system and the deactivation of controlled
mentalization, which is linked with impairments in being able to distinguish between mental states of self and other (Fonagy & Luyten, 2009). This in turn can lead to hypersensitivity and increased susceptibility to interference by other people’s mental states, and the poor integration of the cognitive and affective aspects of mentalization. This combination of impairments may explain why BPD patients are more likely to suffer from interpersonal difficulties, as well as high levels of affect dysregulation and impulsivity (Fonagy & Luyten, 2009). Along with the developmental aspect of this model there is also the neuroscience to underpin it. Neuroimaging studies have highlighted important brain regions in mentalizing including the medial prefrontal cortex, which has been shown to be involved mentalization, in other words when asked to infer the mental states of others (Fletcher et al., 1995; Gallagher et al., 2000; Gilbert et al., 2006). Further, a functional neural network between the ventromedial prefrontal cortex, posterior cingulated/precuneus and temporo-parietal junction when mentalizing the self and other has been identified (Lombardo et al., 2009).

Mentalization Based Treatment (MBT) which was developed on the back of this theory aims to develop the individual’s ability to mentalize and to develop more adaptive interpersonal behaviours (Jorgensen et al, 2013).

In contrast, Dialectic Behavioural Therapy (DBT) which is also used in the treatment of BPD is not based on a theoretical model and instead was a trial by error adaption of behavioural therapy to treat highly suicidal patients (Linehan & Wilks, 2015). DBT development was guided by clinical experience and was an attempt to apply both behavioural principles and social learning theory to suicidal behaviour. It also borrows from the philosophical concept of dialectics. It has evolved to be an individual based treatment program that aims to teach new skills, uses exposure-based techniques to help motivate change, and includes weekly meetings for the therapists to provide peer support (Lieb et al., 2004).
Both DBT and MBT have been the treatment modalities with the most research examining their effectiveness at treating BPD (Stoffers et al., 2012). A recent Cochrane review has shown both treatments to be beneficial with DBT has being found to be effective in reducing self-harm and suicide attempts as well as increasing social adjustment, and MBT being effective at treating the core symptoms of BPD such as interpersonal difficulties (Stoffers et al., 2012). It is interesting that both modalities are effective given one’s lack of theoretical underpinning and direct link to the impact of childhood trauma. Perhaps there are certain treatment modalities which may be of more benefit to patients with BPD who have or have not suffered from childhood trauma. Unfortunately, there is a lack of research in this area to answer this question. Therefore it may be beneficial for future research to examine this in more depth.

This review also highlights the need for more research in the area of the childhood trauma prevalence. First, it would be important to ascertain the effects of different interview methods on the reported prevalence rates of childhood abuse. In the meantime, it is recommended that researchers use the CTQ and SCID-II when investigating childhood abuse within this population. Second, given the large amount of research, a meta-analysis in this area would help to clarify the importance of different types of childhood abuse and neglect in the development of BPD.

Trying to understand potential links between childhood trauma and disorder development is not unique to BPD, suggesting the possibility that there is a generalised association between trauma and complex psychopathology, albeit with nuanced differences between disorders. For instance, there is a significant body of literature suggesting a complex set of associations between types of childhood trauma and specific symptoms of psychosis (e.g. Read et al., 2005; Varese et al., 2012).
In conclusion, the results from this review confirm the existing research that suggests a link between childhood trauma and BPD. They also suggest that abuse type may also have an impact on this link, with emotional abuse appearing to have a stronger link over sexual abuse. However, further population level studies would be necessary to confirm this. Finally, the results of this review also suggest that research in this area is conducted with reasonable levels of methodological integrity, and also highlight the importance of measurement selection.

THESIS AIMS

The main aims of this thesis are two-fold:

1) To examine whether a new Mentalization-Based Therapy (MBT) treatment framework for Borderline Personality Disorder leads to within-patient changes in psychiatric symptoms, using a retrospective case note review.

2) To evaluate predictors for completion of this programme.
PAPER 2: EMPERICAL PAPER

TITLE: A retrospective examination of the effectiveness of a group-only Mentalization Based Therapy Intervention for Borderline Personality Disorder

ABSTRACT

A recent developmental model of Borderline Personality Disorder (BPD) and one that is gaining popularity focuses on mentalization. Following their exposition of this mentalizing model of BPD, Bateman and Fonagy developed the Mentalization Based Treatment (MBT) intervention for BPD (Bateman & Fonagy 2006). This intervention includes both group and individual therapy with the focus on the patient’s relationship with the therapist and other members of the group. Promising evidence that MBT interventions are effective for treating symptoms of BPD is beginning to emerge (Stoffers et al., 2012). The purpose of this study was to examine the effectiveness of a group-only MBT intervention via a retrospective case note review. The results suggest that this group-only adaptation is an effective and well tolerated intervention in regards to drop-out rate. Significant decreases in paranoid ideation and interpersonal sensitivities were found along with decreases overall psychiatric symptom load, depression, and phobic anxiety were observed after the completion of the group. Finally, age and level of histrionic symptoms were found to be significant predictors of group completion, with older patients with less histrionic symptoms being more likely to complete.
INTRODUCTION

Borderline Personality Disorder (BPD) is traditionally thought of as hard to manage and to treat due to the often pervasive symptoms of affect instability, impulsivity, and interpersonal difficulties (Zanarini et al., 2005). Why individuals develop Borderline Personality Disorder (BPD) is still not clearly understood, but it is thought to involve a complex relationship between genetics, adverse childhood events and interpersonal difficulties (Lieb et al., 2004). The psychobiological hypothesis is that genetic factors interact with experiences of early adverse events to cause emotional dysregulation and impulsivity, which in turn could lead to dysfunctional behaviours, such as self-harm, psychosocial conflicts and deficits (Lieb et al., 2004). Indeed, BPD can be thought to be significantly heritable with approximately 42% to 68% of the variance associated with genetic factors (Gunderson, 2011). Further differences in the way the brains of individuals with BPD function such as when exposed to emotions or facial expressions have been found via studies involving magnetic resonance imaging (Gunderson, 2011).

A recent model of BPD development and one that is gaining popularity focuses on mentalization. Mentalizing can be defined as the ability to make sense of ourselves and others, including understanding the behaviours of others in terms of their likely thoughts, wishes, feelings and desires (Bateman & Fonagy, 2008a). There are three dimensions of mentalization: (a) modes of functioning (implicit vs. explicit), (b) objects subject to functioning (self vs. other) and (c) aspects of functioning (cognitive vs. affect; Choi-Kain & Gunderson, 2008). Bateman and Fonagy theorised that this ability develops as a key part of early attachment relationships which, if disrupted, can lead to the symptoms associated with BPD. It is hypothesised that it is the primary caregiver’s marked and contingent mirroring of a child’s internal states within a secure attachment relationship that allows the child to develop a capacity to mentalize. In this model the disruption is often due to psychological trauma such as abuse suffered during early childhood. As a result of this disruption the
individual may be left with a lower threshold for both the activation of the attachment system and the deactivation of controlled mentalization, which may result in difficulty differentiating between the mental state of the self and others. This difficulty may then leave the individual susceptible to being influenced by the mental states of others as well as with a poor integration of the cognitive and affective aspects of mentalization. The combination of these difficulties may underpin the high levels of affect dysregulation, impulsivity and interpersonal difficulties often associated with BPD (Fonagy & Luyten, 2009). Along with the developmental aspect of this model there is also neuroimaging evidence to support it. For example, the medial prefrontal cortex, has been shown to be involved mentalization, in other words when asked to infer the mental states of others (Fletcher et al., 1995; Gallagher et al., 2000; Gilbert et al., 2006). Further, a functional neural network between the ventromedial prefrontal cortex, posterior cingulated/precuneus and temporo-parietal junction when mentalizing the self and other has been identified (Lombardo et al., 2009).

It can be argued that mentalization as a concept has overlaps with mindfulness, psychological mindedness, and empathy (Choi-Kain & Gunderson, 2008). First, both mentalization and mindfulness involve directing attention to our own experiences in order to decrease impulsivity and reactivity. Further they both highlight the integration of cognitive and affective aspects of mental states. However they differ in that mindfulness is concerned with the present while mentalization can concern the past, present or future, further while mindfulness aims to accept the internal experience mentalization looks to construct meaning relating to these experiences. Second, psychological mindedness and mentalization are similar with both being interested in how the mind functions, however, psychological mindedness concerns only explicit or conscious consideration of mental states while mentalization involves the implicit consideration as well. Third, while both empathy and mentalization involve the appreciation of the mental states of others, empathy is more other-oriented and implicit while mentalization is both other and self oriented.
Borderline Personality Disorder has been traditionally treated with psychotherapy, psychopharmacology or a combination of the two (Gunderson 2011). The evidence for either type of treatment is not supported by enough good quality evidence (e.g. randomised controlled trials). This unfortunately is not unusual, and there are many disorders without a large randomised controlled trial evidence base for psychological interventions. The most recent systematic review on psychological interventions for BPD examining Dialectic behaviour therapy (DBT), mentalization-based treatments (MBT), cognitive behavioural therapy (CBT), interpersonal therapy (IPT) and transference focused therapy (Stoffer et al, 2012). The results suggested that CBT, IPT and transference focused therapy were not effective in reducing the severity of BPD symptoms. DBT however, was found to be effective in reducing self-harm, suicide attempts as well as increasing social adjustment (Stoffers et al., 2012). DBT is an individual-based treatment program that aims to teach new skills, uses exposure-based techniques to help motivate change, and includes weekly meetings for the therapists to provide peer support (Lieb et al 2004). MBT was also found to reduce the severity of BPD symptoms. While DBT has been shown to reduce self-harm, it has not been shown to change symptoms of depression or hopelessness compared to treatment as usual (Bateman & Fonagy, 1999). MBT on the other hand has been shown to decrease these symptoms (Bateman & Fonagy, 2009). This however may be due to how research trials are designed with many DBT trials having the reduction of self-harm as a primary outcome measure or it may be due to the fact that DBT was originally designed to reduce suicide behaviour (Linehan & Wilks, 2015). Both of these interventions (DBT and MBT) are included in the Matrix, Scotland’s guide to delivering evidence-based psychological therapies (2011) for the treatment of BPD.
Mentalization Based Treatment for BPD

Following their development of the mentalizing model of BPD, Bateman and Fonagy developed the Mentalization Based Treatment (MBT) intervention for BPD (Bateman & Fonagy, 2006). This intervention includes both group and individual therapy with the focus on the patient’s relationship with the therapist and other members of the group. The overall aim of the intervention is to develop the individual’s ability to mentalize and to develop more adaptive interpersonal behaviours (Jorgensen et al, 2013). One potential advantage of MBT is that it has been found to be cost effectiveness compared to treatment as usual as it can be administered by generic mental health professionals (who have received the appropriate training) and has been shown to save money with less medication required and fewer trips to Accident and Emergency Departments (Bateman & Fonagy, 2003).

MBT interventions do not claim to be entirely unique and indeed other therapies do employ techniques to help facilitate mentalization (Fonagy & Bateman, 2007). For example, DBT, CBT and CAT use slightly different language to discuss this concept such as mindfulness, self-states and validation (Fonagy & Bateman, 2007). MBT can also be seen as similar to CBT as they both employ techniques that encourage mentalization, however they differ both in terms of the models of the mind and behaviour, and in their mode of delivery (Bateman & Fonagy, 2006). For instance the roots of CBT can be found in social learning theory, while the roots of MBT are psychoanalytic. Further unlike CBT MBT there is no attempt to examine cognitive distortions outside the current patient-therapist relationship or to focus on the behaviour itself (Bateman & Fonagy, 2006). Overall what is unique about MBT is that it puts mentalization as the main focus of therapy and the main mechanism of change (Fonagy & Bateman, 2007).

Promising evidence that MBT interventions are effective for treating symptoms of BPD is beginning to emerge. Results of a randomised controlled trial comparing MBT with Structured Clinical Management (SCM) demonstrated that those in the MBT group showed a
faster decline in symptom distress including overall psychiatric symptom level, depression and interpersonal problems, as well as suicide attempts and hospitalisation (Bateman and Fonagy, 2009). The same research group have also reported results from a long-term follow-up study following MBT interventions. The results revealed that those in the MBT group had less suicide attempts, fewer hospital admissions, and were taking less medications over the 8 years since the intervention than the treatment as usual group. Further, those in the MBT group were more likely to be employed or in school in the years following treatment (Bateman & Fonagy, 2008b). It is possible that those who returned 8-years later were a naturally self-selecting group of patients who were continuing to do well, which could have biased the results. However, given the high retention rate (only 5 of 41 patients reclined to participate) this is unlikely in this case.

Further trials have also been conducted that have examined the effectiveness of MBT. Jorgensen and colleagues (2013) found that those receiving an MBT intervention were more likely to achieve “recovery” and were significantly less distressed by psychiatric symptoms than patients receiving a supportive group intervention. Bales and colleagues (2012) also found that MBT was an effective intervention: reducing suicide, self-harm and care consumption, and increasing interpersonal functioning. A Cochrane review also suggested that MBT interventions are effective at treating core symptoms of BPD (Stoffers et al 2012). However, they did highlight the need for further research.

A common finding among these studies examining MBT for BPD is an effect on interpersonal functioning. Researchers are finding both a decrease in interpersonal problems (Bateman & Fonagy, 2009) and an increase in interpersonal functioning (Bales et al., 2012; Bateman & Fonagy, 2008b).
Predicting Treatment outcome for patients with BPD

Patients with BPD often require high levels of input from psychiatric services, which often come at a high treatment cost (Answell et al, 2007; National Institute for Mental Health in England 2003) Therefore, along with developing the evidence base for psychological interventions it is also important to be able to predict whether a certain treatment program would suit an individual patient and whether patient factors can predict treatment program completion.

Researchers have begun to investigate whether response to treatment can be predicted for this population. Bellino and colleagues (2015) examined predictors of treatment response in patients receiving Interpersonal Therapy for BPD (IPT-BPD) combined with Fluoxetine. They found that patients with more severe BPD symptomatology, higher levels of fear of abandonment, affective instability and identity disturbance were more likely to show improvement. Similarly, Rusch and colleagues (2008) investigated potential predictors of dropout from a DBT program and found that the patients who dropped out of the program had higher levels of anxiety and experiential avoidance at the start of treatment. Black and colleagues (2009) investigated predictors of response to STEPPS and found that high impulsivity was predictive of dropout, while higher baseline severity of psychiatric symptoms was associated with a greater improvement in both global functioning and BPD-related symptoms.

Bateman and Fonagy (2013) examined whether clinical severity of BPD, including level of symptom distress, and personality disorder traits could predict outcome after receiving either MBT or structured clinical management (SCM) treatments for BPD. They found that none of these factors impacted on treatment outcome in either treatment group. However, they did find that higher clinical severity of BPD may predict greater benefit from MBT over SCM. To-date only one systematic review has examined outcome predictors of psychotherapy for BPD. Barnicot and colleagues (2012) found that irrespective of treatment modality, higher
pre-treatment severity and patient-rated therapeutic alliance were the two main predictors of positive outcomes. Age had no impact on treatment outcome.

**A Group-only adaptation of MBT for BPD**

Having both individual and group components to an intervention can be both labour and cost intensive. If MBT could be delivered in a group-only format then it may be easier and less costly to implement within the NHS. A novel group-only adaptation of MBT for BPD has been developed in the North East of Scotland with routine implementation within local health service pathways for treatment of BPD. The adapted model differs from traditional MBT as it involves only group work and does not also involve individual therapy, and is of shorter duration then the traditional 18 month model lasting only 24 weeks. Further, it is run one day a week for a full day rather than multiple sessions a week. In the traditional model, patients have one individual MBT session and one group MBT session a week. The day is split into two halves: the morning focusing on psychoeducation and the afternoon focusing on therapy. The psychoeducation component has three parts to it: MBT education, going through the Structured Clinical Interview II (SCID-II) as a group, and MBT skills. The first weeks of psychoeducation cover attachment, emotional awareness, intervention plans, mentalization, and communicating with others. These topics are those which are covered by the traditional MBT-I group, which is considered to be an introduction to mentalizing and the pre-treatment phase to MBT (Bateman & Fonagy, 2006). The next weeks of psychoeducation involve the group going through a SCID-II interview together. In the final weeks this section is based on teaching MBT skills, which again is a return to content of the traditional MBT-I group. The morning psychoeducation sessions follow the same protocol for each group and the weekly agendas can be found in Appendix E.

For the entire programme the afternoons are dedicated to group MBT sessions based on the principles set forth by Bateman and Fonagy (2006). During these sessions therapists look for breaks in mentalization, which could be occurring in the room at the time or have occurred
over the past week. Breaks in mentalization are explored within the group looking for reasons as to why it may have gone offline. If this break in mentalization occurs during the group then the therapists will work with the patient or patients and try to re-establish mentalization. This mentalizing practice aims to help the patient to then cope with life stressors, such as with relationships at home or at work, outside of treatment as they will be able to identify their own breaks in mentalization and be able to pause and attempt to re-establish it. In order to ensure that these sessions adhered to the MBT model weekly peer supervision sessions were held after the group to discuss and reflect on that week’s group. Further, the MBT adherence scale (see Appendix E) was also used at some sessions to ensure that sessions remained on model. Therefore, the overall treatment framework has potential to deliver similar outcomes to traditional MBT, but with benefits in cost-effectiveness via use of a group-format.

Rationale for Study

To date most research has focused on RCTs to examine the effectiveness of psychological interventions for BPD. Parallel evidence from the field of CBT in both depression and psychosis suggests reduced effect sizes in routine practice compared with RCT designs (Hans & Hiller, 2013; Nordentoft & Austin, 2014). Little is known about how funded research interventions function in real world services and how effectively they can be implemented. To address these shortfalls in healthcare research, Implementation science has emerged as a promising framework of enquiry with implementation-based research being defined as “scientific investigations that support movement of evidence-base, effective health care approaches from clinical knowledge base into routine use” (Rubenstein & Pugh 2006). Therefore, the purpose of this study was two-fold: first to examine for within-patient changes in psychiatric symptomatology and completion rate of the group-only adaptation of MBT within the context, and second, to examine whether we can identify hypothesised personality or interpersonal factors that would predict treatment completion.
The primary hypothesis was that attending the group-only program would lead to a decrease in overall psychiatric symptoms as well as in specific domains such as depression and interpersonal functioning as seen in studies using the traditional MBT protocol. The SCL-90 was used to test this hypothesis as it has been used in previous research of psychological therapies for BPD, including Bateman and Fonagy’s RCT of MBT. The second hypothesis was that drop-out rates would be of the same magnitude of the traditional MBT treatment model. It was thought based on the available literature base that psychiatric symptom or personality disorder severity might impact on completion of the program. The Personality Diagnostic Questionnaire version 4 (PDQ-4) was used to examine personality disorder traits and diagnoses. It is also possible that a prevalence of childhood trauma may impact on treatment completion. This was hypothesised given the fact that MBT is based on a theoretical model which places importance of childhood trauma on the development of BPD. Therefore data from the Childhood Trauma Questionnaire (CTQ) was collected.

METHODS

In order to examine the effectiveness of a group-only adaptation of MBT a retrospective case note review of all patients who have completed the group since its inception in 2009 was conducted. In addition, semi-structured interviews were conducted with a small sub-sample in order to examine their subjective experience of the group. The first part of the study was deemed not to require ethical approval as it was a service evaluation and was conducted with Caldicott Approval granted by NHS Grampian (Appendix F). Ethical approval however, was sought and obtained for the interviews from the North of Scotland Research Ethics Board (Appendix G).

Measures

Data was collected from the psychotherapy files of all patients who had been referred to the group since it began in 2009 until April 2014. These data included: gender, age, relationship
status, childhood abuse or neglect, personality disorder traits, psychiatric symptoms before and after completing the group, whether the group was completed, clinician’s impression of progress, and therapy offered after group completion. Routinely administered questionnaires were used to gather data on childhood abuse or neglect, personality disorder traits and psychiatric symptoms. A short interview was conducted with a sub-sample of patients between weeks 23 and 24 of the group to ascertain their views on participation in the group.

*Childhood Trauma Questionnaire (CTQ)*

The CTQ is a self-report questionnaire used to retrospectively examine childhood abuse and neglect experiences. Respondents are asked to rate the truth of each item (28 items) based on a 5-point Likert scale from never true to very often true. The instructions and test-items are largely phrased in terms of concrete, objective events and behaviours. Further, terms such as trauma, abuse and neglect are avoided due to their subjective, evaluative and stigmatizing qualities, which can arouse defensiveness (Bernstein et al, 1994). This approach has the advantage of avoiding the above-mentioned terms, which is hypothesised to maximise the accuracy of recall (Brewin et al, 1993). The internal consistencies for this measure are high ranging from .66 for physical neglect to .92 for sexual abuse in an adult sample of psychiatric outpatients (Bernstein & Fink, 1998). Test-retest reliability has also been found to be high with intra-class correlations ranging from .79 for physical neglect to .86 overall (Bernstein & Fink, 1998).

*Symptoms Checklist -90 (SCL-90)*

The SCL-90 is a self-report questionnaire that was originally designed to quantify symptoms in psychiatric outpatients (Derogatis et al, 1973). However, over the years it has evolved into a screening measure of symptom severity across psychiatric populations (Derogatis, 1983) and has become a commonly used outcome measure in research (Bech et al, 1993). The SCL-90 assesses symptom severity across nine different subscales: somatisation, obsessive-compulsive, interpersonal sensitivity, depression, anxiety, hostility, phobic anxiety, paranoid
ideation, and psychoticism. Respondents are asked to rate the occurrence of 90 different symptoms over the past 7 days on a five-point Likert scale. It is then possible to calculate a global index of distress by taking the mean score. This scale was chosen as it has been found to have good reliability and a high internal consistency (Derogatis & Melisaratos 1983). This questionnaire is completed on week 1 of the HUB program and again on week 23. Initial investigations of internal consistency revealed ranges from a low of .77 for psychoticism to a high of .90 for depression (Derogatis et al., 1976), and .79 for paranoid ideation to .90 for depression (Horowitz et al., 1988). Test-retest reliability has also been found to be high ranging from .80 to .90 the different subscales (Derogatis et al., 1976). More recent research has shown a high reliability for the Global severity index (.96; Vallejo et al., 2007).

*Personality Disorder Questionnaire-4 (PDQ-4)*

The Personality Diagnostic Questionnaire (PDQ version 4; Hyler et al, 1988) is a self-report measure used routinely by the department. This measure consists of 99 true/false items, producing scores for 10 different potential personality diagnoses – one for each identified in the DSM-IV-TR personality disorder as well as two personality disorders noted in the DSM-IV-TR appendix. Cut-off scores for each personality classification have been developed and a total score greater than 50 is considered indicative of an increased likelihood of a PD diagnosis. This questionnaire has been used in research to screen for the presence of PDs (Davidson et al, 2001) but has been shown to produce higher rates of the likelihood of a PD diagnosis when compared to a semi-structured interview (Oldham & Skodol, 2000). Internal consistency for this measure has been shown to vary across personality disorders ranging from as low as .42 for obsessive compulsive to .71 for paranoid and schizotypal (Wilberg et al., 2000).

**Statistical Analyses**

All statistical analyses were performed using SPSS version 16 and an alpha level of 0.05 was used throughout. In order to examine changes in psychiatric symptoms the SCL-90
subscales were first tested for normality using the Kolmogorov-Smirnov test and paired t-tests were used to compare pre and post scores. This test of normality was chosen as it is conservative for large samples (Field, 2013). As all SCL-90 subscales were found to be normally distributed there was no need for non-parametric statistics. In order to examine predictability of group completion associations between the pre-group variables were assessed using both point-biserial correlations for normally distributed data and Mann Whitney tests for non-normally distributed variables. Variables that were significantly associated with group completion were then entered into a series of binary logistic regressions to ascertain what factors predicted group completion. Regression models were then compared (Field, 2013). Models were compared to choose which best fit the data by examining for changes in the Chi-Square generated from the Omnibus Test of Model Coefficients. Models ranged from the simplest, with just one predictor, to the most complex with three predictors. The model which explained the most variance above and beyond the most basic model was explored further.

RESULTS

Descriptive Statistics

In total \( n = 152 \) individuals have been referred to the group since it began in 2009. Off these patients \( n = 100 \) went on to complete the group and 52 did not complete, representing a 67% completion rate. Descriptive details of these patients are detailed in Table 1.

Of the patients who had already received their post-group follow up appointment (offered at least 6 weeks post completion) 45.1% had not been offered additional therapy within the department. A chi-square analysis revealed that patients who were deemed to have done well in the group were more likely to received further therapy within the department ($p<.0001$).
Changes in symptoms

Paired-sample t-tests revealed significant decreases in psychiatric distress, both overall ($p=.011$) and for specific symptoms including interpersonal sensitivities ($p=.008$), depression ($p=.008$), phobic anxiety ($p=.022$), paranoid ideation ($p=.001$) and psychoticism ($p=.012$) after completing the group. Effect sizes for these changes ranged from small to medium, with paranoid ideation having the largest (Cohen’s D of 0.44), followed by depression (0.35) and interpersonal sensitivities (0.34). Table 3 details the results of these analyses using scores on the SCL-90 to measure psychiatric distress.

There is, however, a potential problem with conducting a number of comparisons as one increases the potential of detecting a false-positive; in other words detecting a significant difference when one really does not exist. In order to control for this problem the Holm Sequential Bonferroni correction was applied. This method, first described by Holm (1979), is a sequentially rejective method, meaning that hypotheses are rejected one at a time until no further rejections can be done. This method increases the power of detecting more than one correct rejection of the null hypothesis (Holm 1979; Rice 1989) compared to the traditional Bonferroni correction. This method was chosen given the fact that based on previous studies we were expecting more than one significant difference. When this method was applied the following decreases remained significant: paranoid ideation and interpersonal sensitivities, while depression was reduced to a trend.

**Binary Logistic Regressions**

Based on the correlational analyses, the data were fitted to a series of binary logistic regression analyses. The first step in this analysis was to compare the three models: (a) Age, (b) Age and Histrionic symptoms and (c) Age, Histrionic symptoms and Negativistic Symptoms. This sequence of models was chosen based on the strength of the relationship with group completion, starting with the strongest, Age (see Table 4). The results of this analysis revealed a significant change in Chi-Square statistics only when Histrionic symptoms were added to the model. As model B significantly added to the explained variance it was chosen as the model of interest.
Table 5: Results from the Omnibus Tests of Model Co-efficient for the three models of interest.

</table>

The accuracy of the chosen model at correctly classifying individuals as having completed the group or not was 65.5% when only the constant was included and this increased to 70.0% when Age and Histrionic symptoms were added as predictors. The accuracy of the model with only the constant is high due to the fact that in the sample 65% completed the group, which means that for the data assuming a patient completed the group would have been correct 65% of the time. According to the Wald statistic (Field, 2013), both Age (Wald: 6.27, p=.012) and Histrionic symptoms (Wald: 4.58, p=.032) were significant predictors. The overall statistical results from the analysis of Model B can be found in Table 6.

**Interviews**

Six patients completed the post-group interviews to discuss their experiences. The themes that emerged from these interviews was that the patients could see an improvement in their interpersonal functioning having learnt to stop and pause before reacting and to stop before you get carried away. Further they also felt it was beneficial to learn that they were not alone and that others experienced similar difficulties. Some example quotes to illustrate these themes are as follows: said “It was quite nice to see, meet other people that had similar ways of managing and coping with things so you didn’t feel so isolated and odd”, and “Like putting the pause button on and stopping, thinking before and, umm, trying not to revert back you know with every situation, and, umm, just trying to think of the here and now”.

**DISCUSSION**

This first investigation of a group-only adaptation of MBT has produced some promising and important results. First, the results suggest that a group-only MBT intervention is an effective, acceptable (based on drop-out rate) adaptation of the traditional MBT-intervention for treating patients with BPD. Second, it appears that patients who are older and have fewer Histrionic personality symptoms (based on PDQ-4 scores), in other words patterns of
excessively trying to draw attention to oneself, are more likely to complete this group. Third, the prevalence figures of childhood abuse and neglect add to the literature base on the importance of these factors on the development of BPD.

The results comparing pre and post group SCL-90 scores illustrated a decrease in overall psychiatric symptom load and specific domains including interpersonal sensitivities, depression, phobic anxiety and paranoid ideation. Unfortunately, only paranoid ideation and interpersonal sensitivities survived the Holm sequential correction and therefore all other changes shown to be significant pre-correction should be interpreted with caution. However, these results did show similar patterns of decreases in overall psychiatric symptomatology and interpersonal insensitivities as previous studies of traditional MBT interventions (Bateman & Fonagy 2009; Bale et al 2012; Jorgensen et al 2013). For example, the three previous studies demonstrated decreases in the Global Index of Severity (SCL-90), which was also found in the current study. Interestingly, while the current study showed a smaller magnitude of change, the patients in this study had higher levels of psychiatric symptoms prior to treatment, which may have impacted on this. Further, the current study found decreases in depressive symptoms, which was also found by Bateman and Fonagy (2009) using a different measure, the Beck Depression Inventory. This suggests that the group-only intervention is an effective adaptation of the traditional MBT one. However, further research such as an RCT would be necessary to strengthen these findings.

The significant decreases in paranoid ideations and interpersonal sensitivities may also be linked to treatment content. Being curious about other people’s minds is a central part to mentalizing so it is possible that by encouraging curiosity and trying it out in the group those with paranoid ideations begin to realize that they are not alone in their thinking. It is possible that this realization may then in turn lead to a decrease in symptoms. Similarly, by discussing attachment and inter-personal interactions in the morning psychoeducation groups it is likely that patients are able to increase their insight into their inter-personal styles, making it easier
to work on these issues in the afternoon MBT therapy groups. Then, in the afternoon, by practicing mentalizing and interacting with other patients, to learn to be able to stop and pause before reacting and to see alternative perspectives, all of which would aid in decreasing interpersonal sensitivity symptoms. Further research is necessary to confirm these theories.

One of the proposed advantages of MBT interventions compared to other treatments is that it can be a cost effective treatment due to the group component and the fact that it can be administered by generic mental health professionals (Bateman & Fonagy, 2008b). This group only-adaptation may be an even more cost effective intervention as it does not have the individual therapy component as traditional MBT interventions and is 24 weeks in duration rather than 18 months. Research in regards to the cost-effectiveness of group versus individual therapy in general has been mixed. One systematic review comparing group and individual CBT found that group CBT is more cost-effective when treating depression or children but less cost-effective when treating drugs and alcohol dependency, anxiety or social phobias (Tucker & Oei, 2006). With regards to treatment of BPD, Bateman and Fonagy (2003) were able to demonstrate that MBT (which included both group and individual therapy was more cost-effective than treatment as usual. However, health economic research into the potential added cost effectiveness of this group-only MBT intervention would be necessary to investigate this possibility fully.

There was a low drop-out rate with only 33% of patients not completing the treatment program. This drop-out rate was similar to other studies of MBT interventions, with Bateman and Fonagy (2009) having a drop-out rate of 27%, and Jorgensen and colleagues (2013) a 33% drop-out rate. This suggests that this group-only format is as well tolerated as other MBT interventions due to the similar rates of completion and drop-out from treatment. However, further research with a comparison therapy would be necessary to ascertain
whether this group-only intervention has better retention rates than other forms of therapy for BPD.

It is also possible to compare the results of the current study with other psychological interventions for BPD. For instance, this group-only MBT intervention has a lower drop-out rate of 33% compared to DBT which was been found to have a drop-out rate of 46% (Rusch et al., 2008) and on par with Systems Training for Emotional Predictability and Problem Solving (STEPPS) when used as an add on treatment (Blum et al., 2008), and lower then when STEPPS is used as a stand-alone (47% drop-out rate; Alesiani et al., 2014). Further, like these two other treatments, this group-only approach was able to reduce overall psychiatric symptom loads. However, as different measures were used this prevents a direct comparison. Ideally, a RCT comparing this group-only MBT intervention with either DBT or STEPPS would be conducted in the future to allow for a direct comparison.

The data from this study also fit well with the mentalizing model of BPD. As discussed earlier, this model proposes that in BPD a lack of mentalizing may be associated with interpersonal difficulties and emotional dysregulation (Fonagy & Luyten, 2009). By focusing on increasing mentalization capacity within this group intervention via psychoeducation and group therapy patients experienced a drop in interpersonal difficulties and overall psychiatric symptom load. While mentalization capacity was not able to directly measured in this study it suggests a direction for future research into this group-only adaptation of MBT.

When interpreting the results of this study it is also important to consider the intrinsic healing nature of groups and the common healing factors associated with any psychological treatment. For example, the work of Wampold and Impel (2015) has shown that almost 70% of the effectiveness of psychotherapy can be accounted for by factors such as the therapeutic alliance, and adherence to the therapeutic protocol, which are common among all established forms of psychotherapy. Further, research has shown that there are similar common factors
in group psychotherapy, including group cohesion, and allegiance to the group (Budman et al., 1988). Therefore, it is likely that some of the change observed in this study is due to these common factors.

In addition to these factors one also has to mindful of allegiance effects as research has shown that the therapist’s background, therapy style and choice of intervention can impact on therapy outcomes (Nathan et al., 2000). While these might impact on our results the therapists involved in delivering the groups in this study came from multiple backgrounds including nursing, psychiatry and clinical psychology. Further, they varied in their level of training and interest in MBT. Therefore, it is likely that allegiance effects would not have such an impact on our results as in studies where only one therapist or therapists from one background are used.

This study demonstrates that patients who are older and have fewer Histrionic personality symptoms, in other words problematic interpersonal styles which involve drawing attention to one, are more likely to complete the group. However, it should be noted that even though these are significant predictors of completion they only explain a small percentage of the variance. As seen in the binary logistic regression there is only a 5% increase in prediction accuracy when age and histrionic symptoms were added to the model. It is possible to argue that while these variables may be statistically significant predictors they may not be clinically relevant ones. The odds ratios for age and histrionic symptoms were both suggestive of small effect sizes close to 1, which is the threshold at which the direction of the effect changes (Field, 2013). On the other hand, there is evidence to support those BPD patients with higher levels of histrionic personality symptoms are more likely to drop out of treatment (Alesiani et al., 2014). It is also possible for sexualized mentalization by a father could lead to histrionic symptoms in patients. This may be due to a confused self-image as both a little “temptress” to their father and one who rouses their mother’s jealous hostility leading to difficult interpersonal styles and the need for attention (Herman, 2000).
Another important factor to consider is that with such a high completion rate (65% in our sample) by guessing a patient completed the group one would be correct 65% of the time. Consequently, there is a relatively small proportion of unexplained variance (only 35%) in the current sample. By taking age and histrionic symptoms into account leaves only 30% left to be explained, which raises the question what factors make up the unexplained 30%? Further research would be necessary to explore this issue further.

Unlike previous research (Bellino et al., 2015; Rusch et al., 2008; Black et al., 2009) the current study did not find any association between pre-intervention levels of overall psychiatric symptom load or more specific symptoms such as anxiety or paranoia and completion of the group. This may be due to the fact the previous literature has used other types of interventions rather than MBT based ones, and this is the first time that an MBT intervention has been examined in this manner. In this research all the interventions studied had individual therapy components to them; therefore it is possible that the group only nature of this intervention means that pre-treatment symptom load does not impact on completion.

The role of adverse events during childhood, namely childhood trauma, in the development of BPD has been quite extensively researched (Briere & Elliot, 2003; Boronvalova et al., 2006; Watson et al., 2006). The data from the CTQ adds to the literature on the prevalence of childhood abuse in individuals with BPD. In our large sample of BPD patients there was a high prevalence of emotional abuse, with 71.6% of the population reporting moderate to severe levels. On the other hand, 51.6% reported moderate to severe levels of sexual abuse. Similar prevalence figures were also found in the case series. These prevalence figures fit well both with Perrin and colleagues 2015 systematic review, which showed higher prevalence’s of emotional abuse than sexual abuse and with a meta-analysis conducted by Fossati and colleagues (1999) which found only a moderate association between childhood
sexual abuse and BPD. They also lend support to the theory that the patients involved in the group that was studied resembles the general BPD population.

Of interest we did not find a relationship between childhood abuse and group completion. This may be due to the fact that such a large proportion of the sample had experienced some form of childhood abuse, leaving very few patients who had not experienced any abuse to allow for any association to be found. It is also possible that this high level of abuse prevalence makes this group an appropriate choice of intervention for BPD, as the theory of mentalization is underpinned by the experience of adverse childhood events. Further research however would be necessary to support this hypothesis.

There are several limitations to the current study. The first is that there was no comparison or control group. This means that it is not possible to determine how much of the observed changes in symptoms and functioning was due to attending the group-only MBT intervention and how much may simply be due to the passage of time or the healing factors associated with attending a group. However, given that the observed changes were similar domains to those seen in previous research of MBT interventions it is likely that at least some of the observed changes are due to the intervention. The only way, to answer this question with any certainty would be to conduct further a RCT comparing this group-only MBT intervention with another intervention or a waiting-list control.

Another limitation was that we were not able to investigate the mechanisms of change, in other words what drove the observed decreases in symptomatology, was it the focus on mentalization, was it intrinsic healing factors associated with groups (Yalom & Leszcz, 2005), or a combination of the two. Given previous research showing that MBT was more effective than a supportive psychotherapy group (Bales et al., 2012) it is most likely a combination of the focus on mentalization and the healing factors associated with group therapy. In addition, the small interview sample also suggests that both mentalization and
generic group factors may have driven the observed changes. However, further research such as a case series would be of benefit to help to tease these factors apart.

The final main limitation to this study was that we were not able to investigate whether there is a change in mentalizing capacity following group completion. Mentalization has been notoriously difficult to operationalize and measure in research. This may be due to the fact that an individual’s mentalizing capacity might vary on the different polarities of mentalizing which include: a) automatic-controlled, b) internally focused-externally focused, c) self-other orientation, and d) cognitive-affective processes, and therefore a complete measure would need to consider all these polarities. Fonagy and colleagues (1998) have developed a reflective functioning measure for the Adult Attachment Interview and there have been attempts to develop questionnaires which tap into the different polarities of mentalizing such as the Beliefs about Emotions Scale (Rimes & Chalder 2010) or the Psychologically Mindedness Scale (Shill & Lumley 2002) but none that measure them all. This leaves researchers either having to administer multiple questionnaires to try to cover all the polarities or limiting their investigation to specific polarities. Therefore, it would be beneficial to develop a questionnaire which measures all of the polarities in order to aid in future research of MBT interventions.

The history effect, which is when extraneous variables over which the researchers have no control may impact the results, may also be worth considering as having potential impact on the results of this study. For example, there are factors such as changes in medication and support from the community mental health team, which have the potential to impact on psychiatric symptom level, that were not measured in this study. It is possible that given the group runs for 24 weeks that changes in these domains may occur and could impact on the functioning of the participants. Therefore, it would be important in future research to measure such variables so that they can be added as co-variates to statistical analyses as required.
A limitation of the predictability analysis is that the data is based on a retrospective case note review rather than a prospective study designed specifically to examine predictability of group completion. Therefore, our lack of finding clinically relevant predictors of group completion does not necessarily suggest that they do not exist, simply that they were not contained in the data we had available. Given that this group is an intervention based on mentalization it could be hypothesised that reflective functioning or mentalizing capacity may be associated with completion. It is also possible that attachment style may be an important predictor of completion. Research by Fonagy and colleagues (1996) has suggested that BPD patients with a dismissing attachment style were more likely to gain benefit from psychotherapy. Therefore, it is possible that more entrenched unresolved attachment styles may make patients less likely to complete. This idea is supported by Levy and colleagues (2006) who found that BPD patients with an unresolved attachment style prior to therapy were less likely to show any changes in this domain. It is possible that those with unresolved attachment styles have more experiences of childhood trauma making it more difficult for these individuals to focus on the here and now, which is the basis of MBT interventions. Previous research has shown that BPD patients with high levels of childhood trauma are more likely to show more unresolved attachment styles, lower reflective functioning and less resolution of loss during psychotherapy (Fonagy et al., 1996; Levy et al., 2006). However, further research is necessary in order to explore these potential relationships.

**Future Research**

The results of this paper open up exciting research avenues. First, conducting an in-depth case series of patients attending this group-only intervention would allow one to track changes in symptomatology over the course of the intervention and to ascertain whether different symptoms such as interpersonal difficulties or paranoid ideation have the same patterns of change. For example, by administering the Inventory of Interpersonal Problems (Horowitz et al, 1988), a well-used measure of interpersonal functioning, at numerous time-
points over the course of the group it would be possible to ascertain whether there is a linear
decrease in symptoms or whether there is perhaps a relationship between content from the
morning session and symptom levels.

Second it is important to conduct a study with a wait list control. This would allow
researchers to assess what changes are a result of the group and which are due to the passage
of time. Further, as discussed above, it would be of interest to conduct an RCT comparing
this MBT group-only intervention with a supportive therapy group or other group
intervention for BPD. This would allow researchers to ascertain what changes or level of
changes in symptoms are unique to this group therapy and which are common to a generic
group therapy for BPD.

Lastly, it would be of interest to measure mentalizing capacity over the course of this group
and other MBT interventions. Such a measure could ascertain whether there is a correlation
between mentalizing capacity and symptom reduction. However, as mentioned earlier there
is no one good measure of all the polarities of mentalization and therefore multiple
questionnaires would be needed or else a new one developed.

In conclusion, the results of this paper demonstrates preliminary evidence that a group only
24-week MBT intervention may be an effective and well tolerated (in terms of drop-out rate)
treatment for BPD. Second, it demonstrates that an MBT intervention can be successfully
implemented in NHS Scotland with similar retention rates and treatment effects seen in
RCTs and other research funded studies of MBT.
REFERENCES

APPENDIX A

GUIDE FOR AUTHORS

Description
Founded in 1961 to report on the latest work in psychiatry and cognate disciplines, the Journal of Psychiatric Research is dedicated to innovative and timely studies of four important areas of research:

(1) clinical and translational studies of all disciplines relating to psychiatric illness, as well as normal human behaviour, including biochemical, physiological, genetic, environmental, social, psychological and epidemiological factors;
(2) basic studies pertaining to psychiatry in such fields as neuropsychopharmacology, neuroendocrinology, electrophysiology, genetics, experimental psychology and epidemiology;
(3) the growing application of clinical laboratory techniques in psychiatry, including imaging and spectroscopy of the brain, molecular biology and computer sciences;
(4) advances in basic and clinical research methodology, including the process of "bench-to-bedside" transfer of new research findings.

The Editors-in-Chief will accept papers of high scientific caliber, after appropriate revision, if necessary, and will aim for their rapid publication. In addition, the Journal will be enhanced by the inclusion of commissioned reviews, news items, book notices and letters to the Editors.

BEFORE YOU BEGIN

Submissions types and word limits
Journal of Psychiatric Research considers three types of manuscripts for possible publication:

1. Original articles: Original articles are limited to 4,000 words in the text body, excluding abstract, references, figure legends, acknowledgement and disclosures.
2. Review articles: Review articles should not exceed 6,000 words.
3. Letters to the Editor: Letters to the Editor may be considered for publication if they include important comments on previous papers in the Journal or preliminary findings of importance. The text should not exceed 1,000 words. One figure or one table may be included.

Queries
Authors may send queries concerning the submission process or journal procedures to the appropriate editorial office. Corresponding authors from the United States, Canada or Latin America may contact Rebecca Wyse at rwyse@stanford.edu. Authors from all other countries may contact Mrs. Anna-Maria Proebstl at jpr@mplpsykl.mpg.de.

For further details on how to submit online, please visit www.elsevier.com/submissionsupport

Ethics in publishing
For information on Ethics in publishing and Ethical guidelines for journal publication see http://www.elsevier.com/publishingethics and http://www.elsevier.com/journal-authors/ethics.

Ethical Considerations
Authors of reports on human studies, especially those involving placebo, symptom provocation, drug discontinuation, or patients with disorders that may impair decision-making capability, should consider the ethical issues related to the work presented and include (in the Methods and Materials section of their manuscript) detailed information on the informed consent process, including the method or methods used to assess the subject's capacity to give informed consent, and safeguards included in the study design for protection of human subjects. Specifically, authors should consider all ethical issues relevant to their research, and briefly address each of these in their reports. When relevant patient follow-up data are available, this should also be reported. Specifically, investigators reporting on research involving human subjects or animals must have prior approval from an institutional review board. This approval should be mentioned in the methods section of the manuscript. In countries where institutional review boards are not available, the authors must include a statement that research was conducted in accordance with the Helsinki Declaration as revised 1980. All studies involving animals must state that the authors followed the guidelines for the use and care of laboratory animals of the author's institution or the National Research Council or any national law pertaining to animal research care.
**Conflict of interest**

All authors must disclose any financial and personal relationships with other people or organizations that could inappropriately influence (bias) their work. Examples of potential conflicts of interest include employment, consultancies, stock ownership, honoraria, paid expert testimony, patent applications/registrations, and grants or other funding. If there are no conflicts of interest then please state this: 'Conflicts of interest: none'. See also [http://www.elsevier.com/conflictsOfInterest](http://www.elsevier.com/conflictsOfInterest).

Further information and an example of a Conflict of Interest form can be found at: [http://help.elsevier.com/app/answers/detail/a_id/286/p/7923](http://help.elsevier.com/app/answers/detail/a_id/286/p/7923).

**Submission declaration**

Submission of an article implies that the work described has not been published previously (except in the form of an abstract or as part of a published lecture or academic thesis or as an electronic preprint, see [http://www.elsevier.com/sharingpolicy](http://www.elsevier.com/sharingpolicy)), that it is not under consideration for publication elsewhere, that its publication is approved by all authors and tacitly or explicitly by the responsible authorities where the work was carried out, and that, if accepted, it will not be published elsewhere including electronically in the same form, in English or in any other language, without the written consent of the copyright-holder.

**Contributors**

Each author is required to declare his or her individual contribution to the article: all authors must have materially participated in the research and/or article preparation, so roles for all authors should be described. The statement that all authors have approved the final article should be true and included in the disclosure.

**Changes to authorship**

This policy concerns the addition, deletion, or rearrangement of author names in the authorship of accepted manuscripts:

*Before the accepted manuscript is published in an online issue*: Requests to add or remove an author, or to rearrange the author names, must be sent to the Journal Manager from the corresponding author of the accepted manuscript and must include: (a) the reason the name should be added or removed, or the author names rearranged and (b) written confirmation (e-mail, fax, letter) from all authors that they agree with the addition, removal or rearrangement. In the case of addition or removal of authors, this includes confirmation from the author being added or removed. Requests that are not sent by the corresponding author will be forwarded by the Journal Manager to the corresponding author, who must follow the procedure as described above. Note that: (1) Journal Managers will inform the Journal Editors of any such requests and (2) publication of the accepted manuscript in an online issue is suspended until authorship has been agreed.

*After the accepted manuscript is published in an online issue*: Any requests to add, delete, or rearrange author names in an article published in an online issue will follow the same policies as noted above and result in a corrigendum.

**Copyright**

Upon acceptance of an article, authors will be asked to complete a 'Journal Publishing Agreement' (for more information on this and copyright, see [http://www.elsevier.com/copyright](http://www.elsevier.com/copyright)). An e-mail will be sent to the corresponding author confirming receipt of the manuscript together with a 'Journal Publishing Agreement' form or a link to the online version of this agreement.

Subscribers may reproduce tables of contents or prepare lists of articles including abstracts for internal circulation within their institutions. Permission of the Publisher is required for resale or distribution outside the institution and for all other derivative works, including compilations and translations (please consult [http://www.elsevier.com/permissions](http://www.elsevier.com/permissions)). If excerpts from other copyrighted works are included, the author(s) must obtain written permission from the copyright owners and credit the source(s) in the article. Elsevier has preprinted forms for use by authors in these cases: please consult [http://www.elsevier.com/permissions](http://www.elsevier.com/permissions).

For open access articles: Upon acceptance of an article, authors will be asked to complete an 'Exclusive License Agreement' (for more information see [http://www.elsevier.com/OAlicense](http://www.elsevier.com/OAlicense)). Permitted third party reuse of open access articles is determined by the author's choice of user license (see [http://www.elsevier.com/openaccesslicensing](http://www.elsevier.com/openaccesslicensing)).

**Author rights**
As an author you (or your employer or institution) have certain rights to reuse your work. For more information see http://www.elsevier.com/copyright.

Role of the funding source
You are requested to identify who provided financial support for the conduct of the research and/or preparation of the article and to briefly describe the role of the sponsor(s), if any, in study design; in the collection, analysis and interpretation of data; in the writing of the report; and in the decision to submit the article for publication. If the funding source(s) had no such involvement then this should be stated.

Funding body agreements and policies
Elsevier has established a number of agreements with funding bodies which allow authors to comply with their funder’s open access policies. Some authors may also be reimbursed for associated publication fees. To learn more about existing agreements please visit http://www.elsevier.com/fundingbodies.
After acceptance, open access papers will be published under a noncommercial license. For authors requiring a commercial CC BY license, you can apply after your manuscript is accepted for publication.

Open access
This journal offers authors a choice in publishing their research:

Open access
- Articles are freely available to both subscribers and the wider public with permitted reuse
- An open access publication fee is payable by authors or on their behalf e.g. by their research funder or institution

Subscription
- Articles are made available to subscribers as well as developing countries and patient groups through our universal access programs (http://www.elsevier.com/access).
- No open access publication fee payable by authors.

Regardless of how you choose to publish your article, the journal will apply the same peer review criteria and acceptance standards.

For open access articles, permitted third party (re)use is defined by the following Creative Commons user licenses:
Creative Commons Attribution-NonCommercial-NoDerivs (CC BY-NC-ND)
For non-commercial purposes, lets others distribute and copy the article, and to include in a collective work (such as an anthology), as long as they credit the author(s) and provided they do not alter or modify the article.

The open access publication fee for this journal is USD 2500, excluding taxes. Learn more about Elsevier’s pricing policy: http://www.elsevier.com/openaccesspricing.

Language (usage and editing services)
Please write your text in good English (American or British usage is accepted, but not a mixture of these). Authors who feel their English language manuscript may require editing to eliminate possible grammatical or spelling errors and to conform to correct scientific English may wish to use the English Language Editing service available from Elsevier’s WebShop (http://www.elsevier.com/webshop/languageediting/) or visit our customer support site (http://support.elsevier.com) for more information.

Informed consent and patient details
Studies on patients or volunteers require ethics committee approval and informed consent, which should be documented in the paper. Appropriate consents, permissions and releases must be obtained where an author wishes to include case details or other personal information or images of patients and any other individuals in an Elsevier publication. Written consents must be retained by the author and copies of the consents or evidence that such consents have been obtained must be provided to Elsevier on request. For more information, please review the Elsevier Policy on the Use of Images or Personal Information of Patients or other Individuals, http://www.elsevier.com/patient-consent-policy. Unless you have written permission from the patient (or, where applicable, the next of kin), the personal details of any patient included in any part of the article and in any supplementary materials (including all illustrations and videos) must be removed before submission.
Submission
Our online submission system guides you stepwise through the process of entering your article details and uploading your files. The system converts your article files to a single PDF file used in the peer-review process. Editable files (e.g., Word, LaToX) are required to typeset your article for final publication. All correspondence, including notification of the Editor's decision and requests for revision, is sent by e-mail.

Submit your article
Please submit your article via http://ees.elsevier.com/jpsychires.

Review Process
Papers, except invited reviews, will be evaluated by at least two external experts. The authors are invited to propose four potential referees, including their names, affiliations, and institution-based E-mail addresses. However, the Editors will exclusively make the choice of reviewers. The authors will be notified as soon as possible whether a contribution is accepted for publication in the form that it was submitted, acceptable after a revision (which, in general, will be reviewed again), or rejected.

PREPARATION

Article Structure
Required Submission Files
When submitting a manuscript to Journal of Psychiatric Research online, authors will receive the following prompts: select article type; enter title; add/edit/remove authors; submit abstract; enter keywords; select classifications; suggest reviewers; request editor; and attach files.
Once the preliminary submission fields have been completed, authors will be asked to upload the documents listed below as separate files. The first six: acknowledgement, conflict of interest, contributors, cover letter, manuscript, and role of the funding source are mandatory and starred (*); the remaining four: figure(s), supplementary material, table(s) and video still are optional.

Please note the following: Do not include the required author disclosures, conflict of interest, contributors, and role of funding source in the main manuscript, only as separate, uploaded files. Furthermore, please note that the title, abstract, and keywords are entered in their appropriate fields within the submission system AND within the beginning pages of the manuscript file.

Cover Letter
The cover letter should briefly explain the uniqueness of the submitted work or summarize the improvements in case of a revised manuscript. For revisions, please include an additional letter that includes point-by-point responses to all Editor and/or Reviewer concerns.

Introduction
State the objectives of the work and provide an adequate background, avoiding a detailed literature survey or a summary of the results.

Material and methods
Provide detailed information regarding the study population investigated and methods used. Thoroughly explain statistical procedures.
For studies reporting results obtained in humans, include a statement that 1) the investigation was carried out in accordance with the latest version of the Declaration of Helsinki, 2) the study design was reviewed by an appropriate ethical committee, and 3) informed consent of the participants was obtained after the nature of the procedures had been fully explained.
For studies reporting experiments on animals, include a statement that researchers followed relevant institutional and national guidelines for both the care and use of laboratory animals.

Results
Results of the study may be represented in tables or figures, as authors deem appropriate. However, do not duplicate presentation (e.g. do not repeat numerical data from tables in the text). It is not appropriate to present means or medians exclusively; please also provide measures of values distribution.

Discussion
This should explore the significance of the results of the work, not repeat them. A combined Results and Discussion section is often appropriate. Avoid extensive citations and discussion of published literature. Discussion of study results should be placed within the appropriate context of knowledge and include discussion of study limitations and implications for future work.
Essential title page information

- **Title.** Concise and informative. Titles are often used in information-retrieval systems. Avoid abbreviations and formulae where possible.
- **Author names and affiliations.** Please clearly indicate the given name(s) and family name(s) of each author and check that all names are accurately spelled. Present the authors' affiliation addresses (where the actual work was done) below the names. Indicate all affiliations with a lower-case superscript letter immediately after the author's name and in front of the appropriate address. Provide the full postal address of each affiliation, including the country name and, if available, the e-mail address of each author.
  - **Corresponding author.** Clearly indicate who will handle correspondence at all stages of refereeing and publication, also post-publication. Ensure that the e-mail address is given and that contact details are kept up to date by the corresponding author.
- **Present/permanent address.** If an author has moved since the work described in the article was done, or was visiting at the time, a 'Present address' (or 'Permanent address') may be indicated as a footnote to that author's name. The address at which the author actually did the work must be retained as the main, affiliation address. Superscript Arabic numerals are used for such footnotes.

Abstract

Please include an abstract of no more than 250 words in single paragraph format.

Highlights

Highlights are mandatory for this journal. They consist of a short collection of bullet points that convey the core findings of the article and should be submitted in a separate editable file in the online submission system. Please use 'Highlights' in the file name and include 3 to 5 bullet points (maximum 85 characters, including spaces, per bullet point). See http://www.elsevier.com/highlights for examples.

Keywords

Immediately after the abstract, provide a maximum of 6 keywords, using American spelling and avoiding general and plural terms and multiple concepts (avoid, for example, 'and', 'of'). Be sparing with abbreviations; only abbreviations firmly established in the field may be eligible. These keywords will be used for indexing purposes.

Artwork

Electronic artwork

General points

- Make sure you use uniform lettering and sizing of your original artwork.
- Embed the used fonts if the application provides that option.
- Aim to use the following fonts in your illustrations: Arial, Courier, Times New Roman, Symbol, or use fonts that look similar.
- Number the illustrations according to their sequence in the text.
- Use a logical naming convention for your artwork files.
- Provide captions to illustrations separately.
- Size the illustrations close to the desired dimensions of the published version.
- Submit each illustration as a separate file.

A detailed guide on electronic artwork is available on our website: http://www.elsevier.com/artworkinstructions.

You are urged to visit this site; some excerpts from the detailed information are given here.

Formats

If your electronic artwork is created in a Microsoft Office application (Word, PowerPoint, Excel) then please supply 'as is' in the native document format. Regardless of the application used other than Microsoft Office, when your electronic artwork is finalized, please 'Save as' or convert the images to one of the following formats (note the resolution requirements for line drawings, halftones, and line/halftone combinations given below):

- EPS (or PDF): Vector drawings, embed all used fonts.
- TIFF (or JPEG): Color or grayscale photographs (halftones), keep to a minimum of 300 dpi.
- TIFF (or JPEG): Bitmapped (pure black & white pixels) line drawings, keep to a minimum of 1000 dpi.
- TIFF (or JPEG): Combinations bitmapped line/half-tone (color or grayscale), keep to a minimum of 500 dpi.

Please do not:

- Supply files that are optimized for screen use (e.g., GIF, BMP, PICT, WPG); these typically have a low number of pixels and limited set of colors;
• Supply files that are too low in resolution;
• Submit graphics that are disproportionately large for the content.

Color artwork
Please make sure that artwork files are in an acceptable format (TIFF or JPEG, EPS or PDF, or MS Office files) and with the correct resolution. If, together with your accepted article, you submit usable color figures then Elsevier will ensure, at no additional charge, that these figures will appear in color online (e.g., ScienceDirect and other sites) regardless of whether or not these illustrations are reproduced in color in the printed version. For color reproduction in print, you will receive information regarding the costs from Elsevier after receipt of your accepted article. Please indicate your preference for color: in print or online only. For further information on the preparation of electronic artwork, please see http://www.elsevier.com/authorinstructions.

Please note: Because of technical complications that can arise by converting color figures to ‘gray scale’ (for the printed version should you not opt for color in print) please submit in addition usable black and white versions of all the color illustrations.

Figure captions
Ensure that each illustration has a caption. Supply captions separately, not attached to the figure. A caption should comprise a brief title (not on the figure itself) and a description of the illustration. Keep text in the illustrations themselves to a minimum but explain all symbols and abbreviations used.

Tables
Tables are to be uploaded, numbered consecutively with Arabic numbers. Each table should include a header. Do not use vertical bars. For every variable, the units of measurement should be clearly identified.

References
Citation in text
Please ensure that every reference cited in the text is also present in the reference list (and vice versa). Any references cited in the abstract must be given in full. Unpublished results and personal communications are not recommended in the reference list, but may be mentioned in the text. If these references are included in the reference list they should follow the standard reference style of the journal and should include a substitution of the publication date with either 'Unpublished results' or 'Personal communication'. Citation of a reference as 'In press' implies that the item has been accepted for publication.

Reference management software
Most Elsevier journals have a standard template available in key reference management packages. This covers packages using the Citation Style Language, such as Mendeley (http://www.mendeley.com/features/reference-manager) and also others like EndNote (http://www.endnote.com/support/enstyles.asp) and Reference Manager (http://refman.com/support/rmstyles.asp). Using plug-ins to word processing packages which are available from the above sites, authors only need to select the appropriate journal template when preparing their article and the list of references and citations to these will be formatted according to the journal style as described in this Guide. The process of including templates in these packages is constantly ongoing. If the journal you are looking for does not have a template available yet, please see the list of sample references and citations provided in this Guide to help you format these according to the journal style.

If you manage your research with Mendeley Desktop, you can easily install the reference style for this journal by clicking the link below:
http://open.mendeley.com/use-citation-style/journal-of-psychiatric-research
When preparing your manuscript, you will then be able to select this style using the Mendeley plugins for Microsoft Word or LibreOffice. For more information about the Citation Style Language, visit http://citationstyles.org.

Reference style
Text: All citations in the text should refer to:
1. Single author: the author’s name (without initials, unless there is ambiguity) and the year of publication;
2. Two authors: both authors’ names and the year of publication;
3. Three or more authors: first author’s name followed by ‘et al.’ and the year of publication.
Citations may be made directly (or parenthetically). Groups of references should be listed first alphabetically, then chronologically.
Examples: "as demonstrated in wheat (Allan, 2000a, 2000b, 1999; Allan and Jones, 1999). Kramer et al. (2010) have recently shown ...."

List: References should be arranged first alphabetically and then further sorted chronologically if necessary. More than one reference from the same author(s) in the same year must be identified by the letters 'a', 'b', 'c', etc., placed after the year of publication.

Examples:
Reference to a journal publication:
Reference to a book:
Reference to a chapter in an edited book:
Note shortened form for last page number, e.g., 51–5, and that for more than 6 authors the first 6 should be listed followed by "et al." For further details you are referred to "Uniform Requirements for Manuscripts submitted to Biomedical Journals" (J Am Med Assoc 1997;277:927–34) (see also http://www.nlm.nih.gov/bsd/uniform_requirements.html).

Video data
Elsevier accepts video material and animation sequences to support and enhance your scientific research. Authors who have video or animation files that they wish to submit with their article are strongly encouraged to include links to these within the body of the article. This can be done in the same way as a figure or table by referring to the video or animation content and noting in the body text where it should be placed. All submitted files should be properly labeled so that they directly relate to the video file's content. In order to ensure that your video or animation material is directly usable, please provide the files in one of our recommended file formats with a preferred maximum size of 150 MB. Video and animation files supplied will be published online in the electronic version of your article in Elsevier Web products, including ScienceDirect: http://www.sciencedirect.com. Please supply ‘stills’ with your files: you can choose any frame from the video or animation or make a separate image. These will be used instead of standard icons and will personalize the link to your video data. For more detailed instructions please visit our video instruction pages at http://www.elsevier.com/artworkinstructions. Note: since video and animation cannot be embedded in the print version of the journal, please provide text for both the electronic and the print version for the portions of the article that refer to this content.

Supplementary material
Elsevier accepts electronic supplementary material to support and enhance your scientific research. Supplementary files offer the author additional possibilities to publish supporting applications, high-resolution images, background datasets, sound clips and more. Supplementary files supplied will be published online alongside the electronic version of your article in Elsevier Web products, including ScienceDirect: http://www.sciencedirect.com. In order to ensure that your submitted material is directly usable, please provide the data in one of our recommended file formats. Authors should submit the material in electronic format together with the article and supply a concise and descriptive caption for each file. For more detailed instructions please visit our artwork instruction pages at http://www.elsevier.com/artworkinstructions.

Submission checklist
The following list will be useful during the final checking of an article prior to sending it to the journal for review. Please consult this Guide for Authors for further details of any item.

Ensure that the following items are present:
One author has been designated as the corresponding author with contact details:
• E-mail address
• Full postal address
All necessary files have been uploaded, and contain:
• Keywords
• All figure captions
• All tables (Including title, description, footnotes)
Further considerations:
• Manuscript has been ‘spell-checked’ and ‘grammar-checked’
• References are in the correct format for this Journal

Journal of Personality Disorders

Instructions to Authors

Types of Articles

Regular Articles: Reports of original work should not normally exceed 30 pages (typed, double-lined spaces, and with standard margins, including tables, figures, and references). Occasionally, an author may feel that he or she needs to exceed this length (e.g., a report of a series of studies, or a report that would benefit from more extensive technical detail). In these circumstances, an author may submit a lengthier manuscript, but the author should describe the rationale for a submission exceeding 30 pages in the cover letter accompanying the submission. This rationale will be taken into account by the Editors, as part of the review process, in determining if the increased length is justified.

Invited Essays and Special Articles: These articles provide an overview of broad-ranging areas of research and conceptual formulations dealing with substantive theoretical issues. Reports of large-scale definitive empirical studies may also be submitted. Articles should not exceed 40 pages including tables, figures, and references. Authors contemplating such an article are advised to contact the editor in advance to see whether the topic is appropriate and whether other articles in this topic are planned.

Brief Reports: Short descriptions of empirical studies not exceeding 20 pages in length including tables, figures, and references.

Web-Based Submissions: Manuscripts must be produced electronically using word processing software, double spaced, and submitted along with a cover letter to http://jpd.mssubmit.net. Authors may choose blind or non-blind review. Please specify which option you are choosing in your cover letter. If you choose blind review, please prepare the manuscript accordingly (e.g., remove identifying information from the first page of the manuscript, etc.). All articles should be prepared in accordance with the Publication Manual of the American Psychological Association. They must be preceded by a brief abstract and adhere to APA referencing format.

Tables should be submitted in Excel. Tables formatted in Microsoft Word's Table function are also acceptable. (Tables should not be submitted using tabs, returns, or spaces as formatting tools.)

Figures must be submitted separately as graphic files (in order of preference: tif, eps, jpg, bmp, gif; note that PowerPoint is not acceptable) in the highest possible resolution. Figure caption text should be included in the article’s Microsoft Word file. All figures must be readable in black and white.

Permissions: Contributors are responsible for obtaining permission from copyright owners if they use an illustration, table, or lengthy quote (100+ words) that has been
published elsewhere. Contributors should write both the publisher and author of such material, requesting nonexclusive world rights in all languages for use in the article and in all future editions of it.

References: Authors should consult the publication manual of the American Psychological Association for rules on format and style. All research papers submitted to the Journal of Personality Disorders must conform to the ethical standards of the American Psychological Association. Articles should be written in nonsexist language. Any manuscripts with references that are incorrectly formatted will be returned by the publisher for revision.

Dr Jennifer Perrin
Trainee Clinical Psychologist
Child and Family Mental Health Services
Rosehill House
Royal Aberdeen Children's Hospital
Cornhill Road
Aberdeen
AB25 2ZG

Dear Dr Perrin,

Full title of project: A service evaluation of the HUB program a Mentalization Based Therapy for Borderline Personality Disorder (BPD)

Thank you for seeking the Committee's advice about the above project.

You provided the following documents for consideration:

- Description of the HUB Programme and the process by which the evaluation would take place.

These documents have been considered by the Scientific Officer.

- After review of the document provided, the proposed project is an Audit and would not require approval from the NRES Committees – North of Scotland. However, approval will be required from the Caldecott Guardian to access the required information.

I enclose a copy of our leaflet, “Defining Research”, which explains how we differentiate research from other activities. The Scientific Officer has advised that the project is not considered to be research according to this guidance. Therefore it does not require ethical review by a NHS Research Ethics Committee.

You should check with the NHS Grampian what other review arrangements or sources of advice apply to projects of this type. Guidance may be available from the clinical governance office.

You may wish to check whether the project should be reviewed by the ethics committee within your own institution.
This letter should not be interpreted as giving a form of ethical approval or any endorsement of the project, but it may be provided to a journal or other body as evidence that ethical approval is not required under NHS research governance arrangements.

However, if you, your sponsor/funder or any NHS organisation feels that the project should be managed as research and/or that ethical review by a NHS REC is essential, please write setting out your reasons and we will be pleased to consider further.

Where NHS organisations have clarified that a project is not to be managed as research, the Research Governance Framework states that it should not be presented as research within the NHS.

Yours sincerely

Rachel Venables PhD
Scientific Officer

Enclosure: NRES leaflet – “Defining Research”

Dear Dr Perrin

Study title: A pilot evaluation of the HUB program: a mentalization based therapy for Borderline Personality Disorder
REC reference: 13/NS/0158
IRAS project ID: 139224

Thank you for your letter of 19 December 2013. I can confirm the REC has received the documents listed below and that these comply with the approval conditions detailed in our letter dated 13 December 2013.

Documents received

The documents received were as follows:

<table>
<thead>
<tr>
<th>Document</th>
<th>Version</th>
<th>Date</th>
</tr>
</thead>
<tbody>
<tr>
<td>Covering Letter</td>
<td></td>
<td>19 December 2013</td>
</tr>
<tr>
<td>Participant Information Sheet</td>
<td>2</td>
<td>19 December 2013</td>
</tr>
</tbody>
</table>

Approved documents

The final list of approved documentation for the study is therefore as follows:

<table>
<thead>
<tr>
<th>Document</th>
<th>Version</th>
<th>Date</th>
</tr>
</thead>
<tbody>
<tr>
<td>Covering Letter</td>
<td></td>
<td>19 December 2013</td>
</tr>
<tr>
<td>Interview Schedules/Topic Guides</td>
<td>1</td>
<td>12 November 2013</td>
</tr>
<tr>
<td>Investigator CV: Jennifer Perrin</td>
<td></td>
<td>15 November 2013</td>
</tr>
<tr>
<td>Supervisor's CV: Matthias Schwannauer</td>
<td></td>
<td>16 October 2013</td>
</tr>
<tr>
<td>Supervisor's CV: Angus MacBeth</td>
<td>04</td>
<td>October 2013</td>
</tr>
<tr>
<td>Supervisor's CV: Linda Trelling</td>
<td>26</td>
<td>October 2013</td>
</tr>
</tbody>
</table>
You should ensure that the sponsor has a copy of the final documentation for the study. It is the sponsor's responsibility to ensure that the documentation is made available to R&D offices at all participating sites.

Please quote this number on all correspondence

Yours sincerely

(Handwritten) Irvine

Mrs Carol Irvine
Ethics Co-ordinator
